Sommaire

Loi normale

Cas unidimensionnel

Cas bidimensionnel

Diagramme quantiles-quantiles: qq-plo

Loi normale standard (ou centrée-réduite)

▶ Une v.a. réelle X suit une "loi normale" ou "loi gaussienne" ou "loi de Laplace-Gauss" si sa densité ((ﷺ : probability density function (pdf))) vaut, $\forall x \in \mathbb{R}$:

$$\varphi(x) = \varphi_{0,1}(x) := \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}}$$

▶ Notation: $X \sim \mathcal{N}(0,1)$

Propriétés: $\mathbb{E}(X) = 0$ (espérance nulle) et $\mathbb{V}\mathrm{ar}(X) = \mathbb{E}(X - \mathbb{E}(X))^2 = 1$ (variance unitaire)

Loi normale

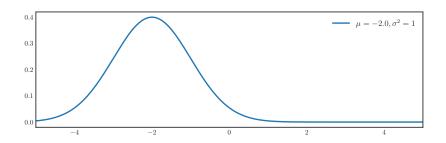

lackbox Une v.a. Y suit une loi normale de paramètres μ et σ^2 si

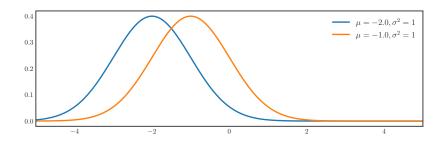

$$Y = \mu + \sqrt{\sigma^2}X$$

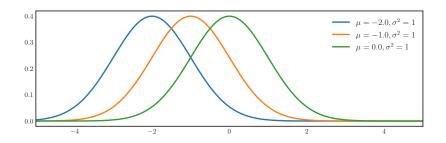

où $X \sim \mathcal{N}(0,1)$, c'est-à-dire si sa densité vaut:

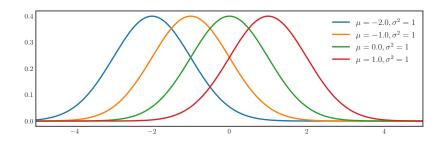

$$\varphi_{\mu,\sigma^2}(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

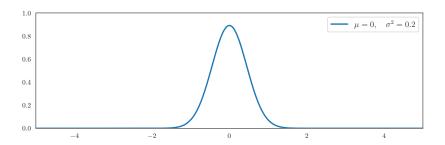

- ► Notation: $Y \sim \mathcal{N}(\mu, \sigma^2)$
- $lackbox{Propriétés: } \mathbb{E}(Y) = \mu \text{ et } \mathbb{V}\mathrm{ar}(Y) = \mathbb{E}(Y \mathbb{E}(Y))^2 = \sigma^2$

Diagramme quantiles-quantiles: qq-plo

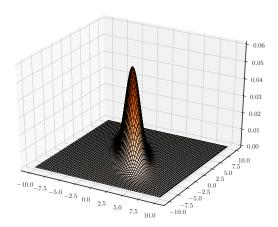

Vecteurs gaussiens (hors programme)

En dimension p, les lois gaussiennes ont des densités de la forme:

$$\varphi_{\mu,\Sigma}(\mathbf{x}) = \frac{1}{(2\pi)^{\frac{p}{2}} \sqrt{|\Sigma|}} \exp\left\{-\frac{1}{2} (\mathbf{x} - \mu)^{\top} \Sigma^{-1} (\mathbf{x} - \mu)\right\}.$$

 $\varphi_{\mu,\Sigma}$: gouvernée par deux paramètres

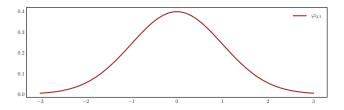

- le vecteur d'espérance $\mu \in \mathbb{R}^p$
- la matrice de covariance $\Sigma \in \mathbb{R}^{p \times p}$ est symétrique

Notation: si le vecteur aléatoire X suit une loi normale d'espérance μ et de covariance Σ (supposée définie positive, *i.e.*, toutes ses valeurs propres sont strictement positives), on note $X \sim \mathcal{N}(\mu, \Sigma)$

Rem: $|\Sigma|=\det(\Sigma)$ est le produit des valeurs propres de Σ . On parle de cas dégénéré quand $\det(\Sigma)=0$

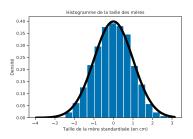

Loi normale

- ► Rôle central en statistique
- ▶ De nombreuses données suivent (approx.) cette loi
- ► Le théorème central limite (TCL) assure que certaines variables aléatoires suivent (approx.) cette loi si n est grand

Lien histogramme-densité et TCL

- Si des données suivent approximativement une loi normale, alors l'histogramme des données centrées réduites doit ressembler à la courbe ci-dessous
- Standardiser les données $x_1, \ldots, x_n : \frac{x_i \bar{x}_n}{s_n}, \quad i = 1, \ldots, n$ (retirer la moyenne, diviser par l'écart-type)

Comparaison: histogramme / loi normale

- Les données semblent être bien représentées par une loi normale
- On peut alors utiliser cette loi pour répondre à des questions statistiques

Calcul des probabilités

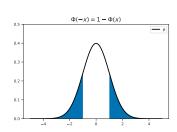

▶ La probabilité d'être plus petit qu'un nombre z correspond à l'aire sous la courbe φ entre $-\infty$ et z

$$\Phi(z) = \int_{-\infty}^{z} \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{x^2}{2}\right) dx$$

 Φ est la **fonction de répartition** (\rightleftharpoons : *Cumulative distribution function (cdf)*) d'une loi normale

Quelques propriétés de Φ

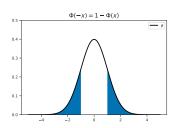

$$\Phi(-x) = 1 - \Phi(x) \text{ (symétrie)}:$$

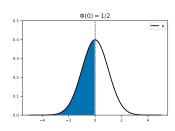

Quelques propriétés de Φ

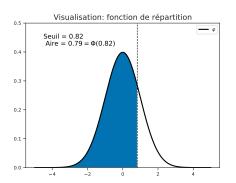

$$\Phi(-x) = 1 - \Phi(x)$$
 (symétrie):

• $\Phi(0) = \frac{1}{2}$ (0 est la médiane):

Visualisation de la fonction de répartition

Exemple de la taille de la mère:

$$\mathbb{P}[\mathsf{Taille} \leq 168] = \mathbb{P}\left[\frac{\mathsf{Taille} - \bar{x}_n}{s_n} \leq \frac{168 - \bar{x}_n}{s_n}\right] \approx \Phi(0.82) = 0.79$$

on calcule la moyenne ($\bar{x}_n=162.7$) et l'écart-type ($s_n=6.428$) de l'échantillon pour obtenir ce nombre

Quantiles gaussiens

Utiliser plutôt:

en Python

```
>>> from scipy.stats import norm # import
>>> norm.ppf(0.95, 0, 1)
1.6448536269514722
```

en R:

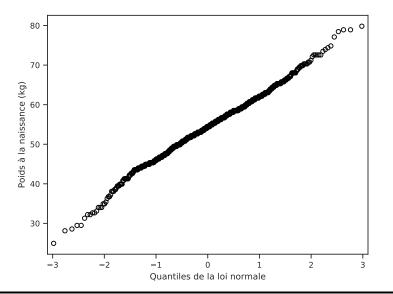

```
>>> qnorm(.95,mean=0,sd=1)
1.6448536269514722
```

Loi normale

Diagramme quantiles-quantiles: qq-plot

Diagramme quantile-quantile⁽¹⁾: exemple

⁽¹⁾M. B. Wilk and R. Gnanadesikan. "Probability plotting methods for the analysis for the analysis of data". In: *Biometrika* 55.1 (1968), pp. 1–17.

Diagrammes quantiles-quantiles (qq-plots)

- ▶ Représentation graphique comparant des distributions de type:
 - observées vs observées
 - observées vs théoriques
 - théoriques vs théoriques
- Utilité des qq-plots:
 - Vérifier si les données suivent une loi particulière
 - Vérifier si deux jeux de données ont la même loi
- Construction pour le cas gaussien: on ordonne l'échantillon x_1, \ldots, x_n en $x_{(1)} \leq \cdots \leq x_{(n)}$ et on affiche les points

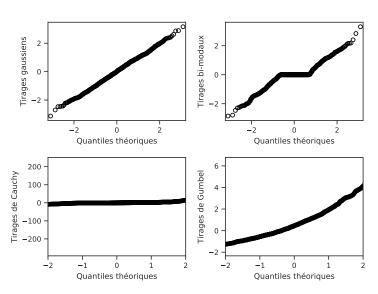

$$\left(\Phi^{-1}\left(\frac{i}{n+1}\right),x_{(i)}\right), \text{ for } i=1,\ldots,n$$

(voir détails en TD / TP)

Interprétation qq-plot poids à la naissance vs loi normale

- ▶ Si les observations étaient $\mathcal{N}(0,1)$ alors le nuage de points se concentrerait autour de la droite y=x
- Si le nuage de points se concentre autour d'une droite mais pas y=x, disons y=ax+b
 - ightharpoonup Si $b \neq 0 \Longrightarrow$ Translation
 - ▶ Si $a \neq 1 \Longrightarrow$ Changement d'échelle

Quelques qq-plots pathologiques (vs. loi normale)
